Gradient descent for multiple variables

Hypothesis:
$$h_{\theta}(x) = \theta^T x = \theta_0 x_0 + \theta_1 x_1 + \theta_2 x_2 + \dots + \theta_n x_n$$

Parameters:
$$\theta_0, \theta_1, \dots, \theta_n$$
 \bigcirc n+1 - director

Cost function:

$$\frac{J(\theta_0, \theta_1, \dots, \theta_n)}{J(\Theta)} = \frac{1}{2m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2$$

Gradient descent:

Repeat
$$\{$$
 $\Rightarrow \theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta_0, \dots, \theta_n)$ \exists (simultaneously update for every $j = 0, \dots, n$)

Gradient Descent

Previously (n=1):

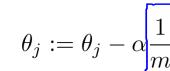

$$\theta_0 := \theta_0 - o \frac{1}{m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})$$

$$\begin{bmatrix} \frac{\partial}{\partial \theta_0} J(\theta) \end{bmatrix}$$

$$i=1$$
(simultaneously undate \hat{H}_0 , \hat{H}_1)

(simultaneously update $\hat{\theta}_0, \theta_1$)

New algorithm $(n \ge 1)$:

$$\theta_j := \theta_j - \alpha \frac{1}{m} \sum_{i=1}^m (h_\theta(x^{(i)}) - y^{(i)}) x_j^{(i)}$$
 (simultaneously update θ_j for

$$j=0,\ldots,n$$
)

Gradient descent in practice I: Feature Scaling

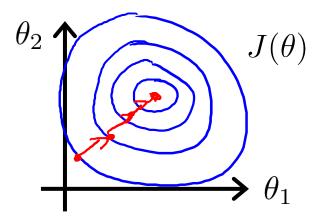

Feature Scaling

Idea: Make sure features are on a similar scale.

E.g. $x_1 = \text{size } (0-2000 \text{ feet}^2) \leftarrow$ x_2 = number of bedrooms (1-5) \leftarrow

$$\Rightarrow x_1 = \frac{\text{size (feet}^2)}{2000}$$

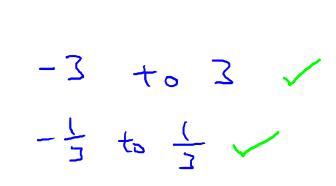

$$\rightarrow x_2 = \frac{\text{number of bedrooms}}{5}$$

Feature Scaling

Get every feature into approximately a

$$\underbrace{-1 \leq x_i \leq 1}_{\text{range.}}$$

Mean normalization

Replace \underline{x}_i with $\underline{x}_i - \mu_i$ to make features have approximately zero mean (Do not apply to $\overline{x}_0 = 1$).

E.g.
$$\Rightarrow x_1 = \frac{size - 1000}{2000}$$

$$x_2 = \frac{\#bedrooms - 2}{5}$$

$$\Rightarrow \begin{bmatrix} -0.5 \le x_1 \le 0.5 \\ -0.5 \le x_2 \le 0.5 \end{bmatrix}$$

- "Debugging": How to make sure gradient descent is working correctly.
- How to choose learning rate α .

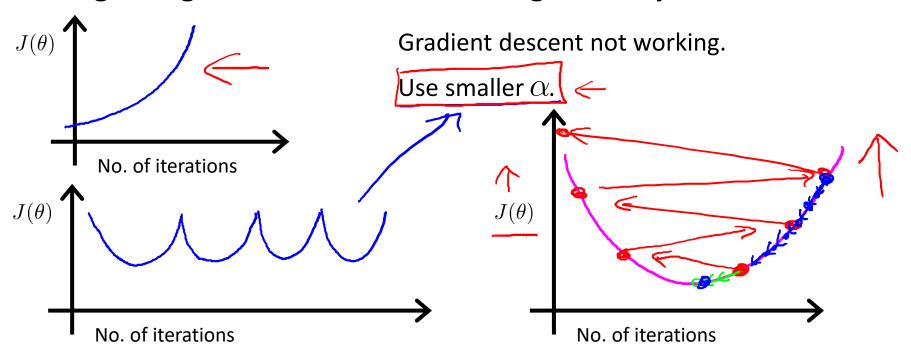

Making sure gradient descent is working correctly.

Example automaticconvergence test:

Declare convergence if $J(\theta)$ decreases by less than 10^{-3} in one iteration.

Making sure gradient descent is working correctly.

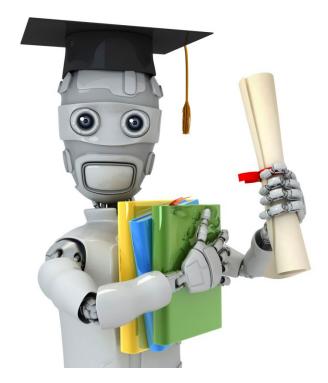

- For sufficiently small lpha, J(heta) should decrease on every iteration.
- But if lpha is too small, gradient descent can be slow to converge.

Summary:

- If α is too small: slow convergence.
- If α is too large: $J(\theta)$ may not decrease on every iteration; may not converge. (Slow converge where α

To choose α , try

Normal equation: Method to solve for θ analytically.

Intuition: If 1D $(\theta \in \mathbb{R})$

$$J(\theta) = a\theta^2 + b\theta + c$$

$$\frac{\partial}{\partial \phi} J(\phi) = \frac{\sec^2 \phi}{\cos^2 \phi}$$
Solve, for ϕ

$$\frac{\theta \in \mathbb{R}^{n+1}}{\frac{\partial}{\partial \theta_j} J(\theta)} = \frac{J(\theta_0, \theta_1, \dots, \theta_m)}{\frac{\partial}{\partial \theta_j} J(\theta)} = \frac{1}{2m} \sum_{i=1}^m (h_{\theta}(x^{(i)}) - y^{(i)})^2$$

Solve for $\theta_0, \theta_1, \dots, \theta_n$
